**ECE 271A** 

Cheetah Image Segmentation Using Expectation Maximization Algorithm

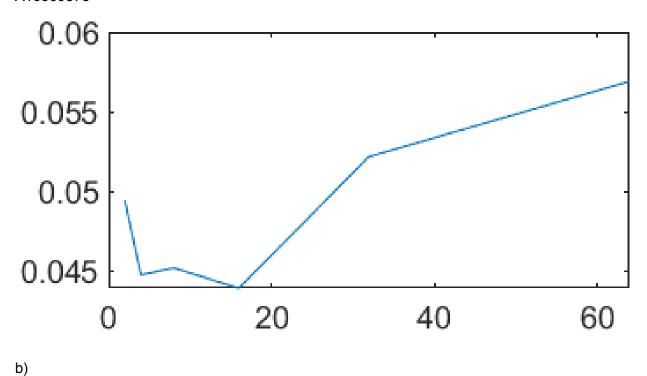

# a) Figure of subplots for all 25 pairs of initializations:

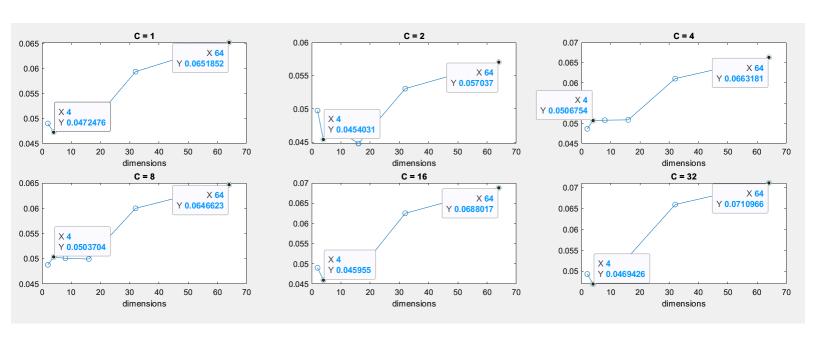

From this figure, it is obvious that different initializations of our mixture parameters will result in small deviations in errors when classifying our cheetah image. Below are two more plots to make that distinction clearer:

This figure shows the plots of errors vs. dimensions used for classification using different amounts of components, C. By inspecting this figure, we can see that using 2 components may be the optimal amount when finding the distribution of the complete data for each of the classes. Changing the number of mixture components has a marked effect on the probability of error for this classification problem because we approach a distribution closer to the true distributions of the complete data of the cheetah and grass classes when we do that. We see that using more than or less than 2 components for the mixtures only increases the probability of error overall.

#### Matlab Code:

```
%% Load Training Data
